

Use rising water levels to store energy

How does energy storage work?

As shown in Fig. 1, in this method, in the energy storage stage, the pump transfers water from the water reservoir to the water tower tank using the energy generated by the turbo-generator installed in the gas pressure reduction station.

How does a gas pressure reduction station store energy?

In order to store the electrical energy generated as a result of energy recovery in the gas pressure reduction station, the pumps transfer water from the water reservoir to the tank above the water tower by consuming that energy and thus store the energy in it.

How does a water tower affect energy storage capacity?

It should be noted that the larger the volume of the tower tank and the height of the tower, the higher the energy storage capacity of the water tower will be. In the discharge stage of the energy storage system, water is released from the tower tank and electric energy is generated by passing through the water turbine.

How much electricity does a water tower based energy storage system use?

According to Table 5, it was observed that the average daily electrical energy consumed to charge the water tower based energy storage system is equal to 3.78(MWh). The amount of electrical energy generated in the discharge stage is calculated using Eq. (53) as 2.415 (MWh).

How does a water storage system work?

In the discharge stage of the energy storage system, water is released from the water tower tank and generates mechanical power by passing through the water turbine. The mechanical power generated by the generator is converted into electrical energy.

What is the best energy storage method based on water pumping?

3.2.1. Energy analysis of energy storage system based on water towers Energy storage in a water tower is a special method of pumped-hydro energy storage system. This energy storage mechanism proposed in this research is the best energy storage method based on water pumping for a gas pressure reduction station.
